

# Parameters and Calibration: The Numeric Foundation

## Purpose

This document is the single source of truth for every numeric parameter in the simulation. When other documents reference a number, this is where the canonical value lives. Agents do not need to memorize these -- the orchestrator uses them internally -- but they provide grounding for what "reasonable" looks like.

## Demand System Parameters

### Multinomial Logit Utility

$$U_i = a * quality_i - b * price_i + g * brand_i + xi_i + eps_i$$
$$U_0 = V_0(t) + macro\_shock + eps_0 \quad (\text{outside option})$$

| Parameter            | Symbol      | Value        | Units             | Notes                 |
|----------------------|-------------|--------------|-------------------|-----------------------|
| Price coefficient    | b           | 0.000015     | per dollar        | Higher price -> lower |
| Quality coefficient  | a           | 1.0          | per quality point | Normalized to 1.0     |
| Brand coefficient    | g           | 0.4          | per brand point   | Brand matters, less   |
| Outside option base  | V_0(0)      | 3.5          | utility units     | High = most people c  |
| Outside option decay | lambda_V0   | 0.03/quarter | per quarter       | As awareness grows,   |
| Outside option floor | V_0_min     | 0.5          | utility units     | Some people will nev  |
| Logit scale paramete | mu          | 1.0          | --                | Standard normalizati  |
| Macro demand shock s | sigma_macro | 0.08         | --                | ~+-16% in extreme qu  |
| Firm taste shock std | sigma_xi    | 0.05         | --                | ~+-10% firm-specific  |

### Potential Market Size

| Parameter                           | Value        | Units                              |
|-------------------------------------|--------------|------------------------------------|
| Base potential patients (Q1 2031)   | 600,000,000  | adults 50+ in high-income countrie |
| Initial awareness rate              | 0.15         | fraction who know SRT exists       |
| Awareness growth (natural)          | 0.02/quarter | per quarter, additive              |
| Awareness growth (per \$1M SGA indu | 0.001        | per quarter per \$1M               |
| Awareness ceiling                   | 0.98         | maximum awareness                  |

### Safety-Adjusted Demand Modifier

The serious adverse event rate adjusts the effective quality score:

| Serious AE Rate | Quality Multiplier | Interpretation                     |
|-----------------|--------------------|------------------------------------|
| > 5%            | 0.5x               | "Experimental, risky" -- halves pe |
| 3-5%            | 0.7x               | "Promising but dangerous"          |
| 1-3%            | 1.0x               | "Acceptable for high-value therapy |
| 0.5-1%          | 1.3x               | "Safe enough for broader adoption" |
| < 0.5%          | 2.0x               | "Routine medical procedure"        |
| < 0.1%          | 3.0x               | "Over-the-counter safe"            |

This multiplier is applied to the quality\_score before entering the logit:

$$\text{effective\_quality\_i} = \text{quality\_score\_i} * \text{ae\_demand\_modifier}(\text{serious\_ae\_rate\_i})$$

## Quality Composite Score

$$\text{quality\_score} = w_{\text{eff}}(t) * \text{efficacy\_index} + w_{\text{saf}}(t) * \text{safety\_index} + w_{\text{con}}(t) * \text{convenience\_index}$$

### Component Indices (0-100 scale)

| Component         | Gen 1 | Gen 2 | Gen 3 | Gen 4 | Calculation       |
|-------------------|-------|-------|-------|-------|-------------------|
| Efficacy index    | 35    | 55    | 75    | 90    | 4 * epigenetic_ag |
| Safety index      | 27    | 75    | 95    | 98    | 100 * (1 - seriou |
| Convenience index | 20    | 50    | 80    | 95    | Lookup by deliver |

### Time-Varying Weights

| Period                | w_eff | w_saf | w_con | Rationale            |
|-----------------------|-------|-------|-------|----------------------|
| Years 1-3 (Q1-Q12)    | 0.50  | 0.30  | 0.20  | Early adopters care  |
| Years 4-7 (Q13-Q28)   | 0.35  | 0.40  | 0.25  | Safety becomes key a |
| Years 8-12 (Q29-Q48)  | 0.25  | 0.40  | 0.35  | Convenience matters  |
| Years 13-20 (Q49-Q80) | 0.20  | 0.35  | 0.45  | Mass market wants ea |

Weights transition linearly between periods (no discontinuity).

## Capability, Brand, and Capacity Stocks

### Capability Stock (A\_it) -- Drives Efficacy/Safety

$$A_t = (1 - \text{delta\_A}) * A_{t-1} + \text{eta\_A} * \text{actual\_product\_rd\_spend}$$

| Parameter                  | Symbol  | Value         | Notes                      |
|----------------------------|---------|---------------|----------------------------|
| Depreciation rate          | delta_A | 0.025/quarter | 10% annual; knowledge dec  |
| Accumulation rate          | eta_A   | 0.8 per \$1M  | \$30M/quarter -> +24 point |
| Starting value (all firms) | A_0     | 35.0          | Baseline Gen 1 quality     |
| Gen 2 threshold            | --      | 120.0         | Stochastic check begins a  |
| Gen 3 threshold            | --      | 280.0         |                            |
| Gen 4 threshold            | --      | 500.0         |                            |

When the stochastic check triggers a generation advance, the efficacy/safety indices jump to the new generation's values (see table above). The capability stock continues to accumulate beyond the threshold, improving efficacy/safety incrementally within a generation.

### Brand Stock (B\_it) -- Drives Brand Utility

$$B_t = (1 - \text{delta\_B}) * B_{t-1} + \text{eta\_B} * \text{actual\_sga\_spend} * \text{quality\_effectiveness}$$

| Parameter                 | Symbol  | Value                  | Notes                      |
|---------------------------|---------|------------------------|----------------------------|
| Depreciation rate         | delta_B | 0.10/quarter           | 40% annual; brand fades f  |
| Accumulation rate         | eta_B   | 1.5 per \$1M           | \$10M/quarter -> +15 point |
| Starting value            | B_0     | 10.0                   | Low initial brand          |
| Quality effectiveness     | --      | effective_quality / 50 | Marketing more effective   |
| Brand crash on safety eve | --      | -30% of current B      | Per publicized AE event a  |

## Capacity Stock (K\_it) -- Drives Max Production

$$K_{\text{effective}_t} = K_{\text{installed}_t} * (1 - \text{aging\_penalty}_t)$$

| Parameter                         | Value                     | Notes                               |
|-----------------------------------|---------------------------|-------------------------------------|
| Starting capacity                 | 250 courses/quarter       | Pilot plant                         |
| Capacity per \$1M capex           | ~4.3 courses/quarter      | At small-commercial scale (\$120M - |
| Build delay                       | 4-8 quarters              | Depends on scale                    |
| Depreciation (PPE)                | 2.5%/quarter of gross PPE | 10% annual                          |
| Aging penalty (no reinvestment)   | +0.5%/quarter after 20Q   | Equipment wear                      |
| Minimum utilization to avoid cost | 70%                       | Below this, COGS multiplier kicks   |

## Cost Structure

### COGS Computation (Per Treatment Course)

```
base_cogs = generation_base_cogs * (1 - process_rd_reduction)
utilization_cogs = base_cogs * utilization_multiplier(capacity_utilization)
final_cogs = utilization_cogs
```

| Generation | Base COGS/course | At Scale                       |
|------------|------------------|--------------------------------|
| Gen 1      | \$14,000         | \$13,600 at 5000+ courses/year |
| Gen 2      | \$7,500          |                                |
| Gen 3      | \$2,500          |                                |
| Gen 4      | \$800            |                                |

Note: The \$14,000 base includes per-firm variation of +/- \$1,000 drawn at firm creation. This is why the dossier example shows \$14,200 while the world doc baseline is \$13,600 (which assumes full commercial scale + process optimization).

### Capacity Utilization Multiplier

| Utilization | COGS Multiplier                     | Formula              |
|-------------|-------------------------------------|----------------------|
| >= 90%      | 1.00                                | --                   |
| 70-90%      | $1.00 + 0.5 * (0.90 - \text{util})$ | Linear interpolation |
| 50-70%      | $1.10 + 1.0 * (0.70 - \text{util})$ | Steeper slope        |
| 30-50%      | $1.30 + 1.5 * (0.50 - \text{util})$ | Even steeper         |
| < 30%       | $1.60 + 2.0 * (0.30 - \text{util})$ | Severe penalty       |

This multiplier is applied to base\_cogs when computing actual COGS posted to the income statement. It captures the fixed-cost absorption effect: when a factory runs below capacity, fixed costs are spread over fewer units.

## Workforce Parameters

### Workforce Mechanics

Workforce size affects operations through three channels:

```
1. R&D speed: More scientists -> faster capability accumulation
effective_eta_A = eta_A * (1 + 0.3 * log(scientists / 50))
At 50 scientists (baseline): multiplier = 1.0x
At 100 scientists: multiplier = 1.21x
At 200 scientists: multiplier = 1.42x
```

2. Manufacturing quality: More ops staff -> lower batch failure rate  

$$\text{batch\_failure\_rate} = \text{base\_rate} * (80 / \text{ops\_staff})^{0.3}$$
  
 At 80 ops staff (baseline): 1.0x base rate  
 At 120 ops staff: 0.88x base rate (fewer failures)  
 At 50 ops staff: 1.15x base rate (more failures)

3. Commercial effectiveness: More sales staff -> higher brand accumulation  

$$\text{effective\_eta\_B} = \text{eta\_B} * (1 + 0.2 * \log(\text{sales\_staff} / 30))$$

## Workforce Cost Model

| Role Category       | Base Annual Salary | Overhead Multiplier        | Total Cost/Employee/Quart |
|---------------------|--------------------|----------------------------|---------------------------|
| Research scientists | \$185,000          | 1.4x (benefits, equipment) | \$64,750                  |
| Process development | \$155,000          | 1.3x                       | \$50,375                  |
| Manufacturing ops   | \$95,000           | 1.25x                      | \$29,688                  |
| Quality assurance   | \$120,000          | 1.3x                       | \$39,000                  |
| Commercial/sales    | \$140,000          | 1.5x (commissions, travel) | \$52,500                  |
| Medical affairs     | \$165,000          | 1.3x                       | \$53,625                  |
| General & admin     | \$130,000          | 1.2x                       | \$39,000                  |

Workforce costs flow into SGA (commercial, G&A), R&D (scientists, process dev), and COGS (manufacturing, QA) proportionally.

## Workforce Decisions and Effects

| Decision                       | Effect                               | Lag                                   |
|--------------------------------|--------------------------------------|---------------------------------------|
| Hire N employees (by category) | +headcount, +cost, +capability aft   | 1 quarter ramp-up (50% effectiveness) |
| Lay off N employees            | -headcount, -cost, restructuring c   | Immediate cost; capacity reduction    |
| Increase compensation X%       | Reduces turnover, improves retention | Immediate cost; retention benefit     |
| Freeze hiring                  | No new hires; natural attrition co   | Gradual headcount decline             |

## Leasing and Facility Decisions

### Lease vs. Build

Firms can choose to LEASE manufacturing capacity instead of building:

| Decision           | Lease                           | Build (Capex)                        |
|--------------------|---------------------------------|--------------------------------------|
| Upfront cost       | \$0                             | Full build cost (e.g., \$120M for s) |
| Quarterly cost     | \$8-12M/quarter (lease payment) | \$2M/quarter (maintenance)           |
| Capacity available | Immediately (next quarter)      | After build delay (4-8 quarters)     |
| Balance sheet      | Operating lease liability (loq) | PPE asset (ppentq)                   |
| Flexibility        | Can terminate with 4Q notice    | Permanent (can idle but not sell)    |
| Customization      | Standard facility               | Fully customized                     |
| Capacity           | Fixed                           | Can expand later                     |

### Lease Accounting

Under the simulation's accounting rules (simplified ASC 842):

- Right-of-use asset: Recorded as part of PPE (ppentq), equal to present value of remaining lease payments

- Lease liability: Recorded as part of other long-term liabilities (loq)
- Lease expense: Recorded as part of COGS (for manufacturing leases) or SGA (for office leases)
- Depreciation: Right-of-use asset is amortized over the lease term

## Compustat Columns for Leases

| Column | Name                      | Source                             |
|--------|---------------------------|------------------------------------|
| rouq   | Right-of-use assets       | PV of remaining lease payments     |
| leaseq | Lease liability (total)   | Same as rouq at inception; diverge |
| xlrq   | Lease expense (quarterly) | Lease payment allocated to P&L     |

## Stock-Based Compensation

### How It Works

Firms grant stock options and restricted stock units (RSUs) to employees as part of compensation. This is especially important in biotech where cash is scarce.

### Firm Decision

Each quarter, firms decide:

```
{
  "stock_comp": {
    "option_grants": 100000,          // number of options granted
    "option_strike_price": "at_market", // at current stock price
    "rsu_grants": 50000,              // number of RSUs granted
    "vesting_quarters": 12             // vest over 12 quarters
  }
}
```

### Accounting Treatment

- Expense: Stock-based compensation is a non-cash SGA expense recognized over the vesting period
- Fair value: Options valued using Black-Scholes at grant date; RSUs valued at grant-date stock price
- P&L impact: Reduces operating income (non-cash)
- Cash flow: Added back to CFO (non-cash expense)
- Dilution: Options/RSUs increase diluted share count when exercised/vested
- EPS impact: Diluted EPS uses higher share count

### Parameters

| Parameter                                      | Value                 |
|------------------------------------------------|-----------------------|
| Typical option grant (% of shares outstanding) | 0.5-2.0% per year     |
| Typical RSU grant (% of shares outstanding)    | 0.3-1.0% per year     |
| Option vesting period                          | 12 quarters (3 years) |
| RSU vesting period                             | 8-16 quarters         |
| Option exercise ratio (employees who exercise) | 70-85%                |

|                                     |                  |
|-------------------------------------|------------------|
| Black-Scholes volatility assumption | 40-60% (biotech) |
| Expected option life                | 2.5 years        |

## Compustat Columns for Stock Compensation

| Column         | Name                             | Source                             |
|----------------|----------------------------------|------------------------------------|
| stkcpq         | Stock-based compensation expense | Fair value of grants / vesting per |
| diluted_shares | Diluted shares outstanding       | Basic + in-the-money options + unv |

## Tax Parameters

| Parameter                    | Value                        | Notes                              |
|------------------------------|------------------------------|------------------------------------|
| Corporate tax rate           | 21%                          | Flat rate, matching US federal     |
| NOL carryforward usage limit | 80% of taxable income        | Per US TCJA rules                  |
| NOL expiration               | None (infinite carryforward) | Simplified from real 20-year limit |
| State taxes                  | 0% (not modeled)             | Simplification                     |
| R&D tax credit               | 0% (not modeled)             | Simplification; could add as regim |
| Withholding on dividends     | 0%                           | Simplification                     |
| Deferred tax asset from NOL  | tax_rate * cumulative_NOL    | Recorded on BS as part of other as |

## Financial Institution Parameters

### Starting Capital (Canonical Values)

| Institution     | Starting Capital | Min Capital Ratio       | Max Single Exposure      |
|-----------------|------------------|-------------------------|--------------------------|
| Investment Bank | \$5,000,000,000  | 5% of AUM               | N/A (equity, not credit) |
| Commercial Bank | \$2,000,000,000  | 8% of total commitments | 25% of capital           |
| Credit Fund     | \$3,000,000,000  | 10% of total deployed   | 20% of capital           |

### Income and Expense

| Parameter         | Investment Bank           | Commercial Bank           | Credit Fund              |
|-------------------|---------------------------|---------------------------|--------------------------|
| Fee income        | 5% of IPO/secondary proce | 0.5%/quarter of commitmen | 0.3%/quarter of deployed |
| Operating expense | 1% of capital annually    | 1% of capital annually    | 1% of capital annually   |
| Interest income   | N/A                       | Revolver balance * rate   | Term debt balance * rate |

### Distress Thresholds (Canonical)

| Capital Ratio     | Status                      | Constraint                        |
|-------------------|-----------------------------|-----------------------------------|
| > 2x minimum      | Well-capitalized            | None                              |
| 1x - 2x minimum   | Adequate                    | Mild caution                      |
| 0.5x - 1x minimum | Undercapitalized            | Cannot increase commitments; rate |
| 0 - 0.5x minimum  | Critically undercapitalized | No new business; max rates        |
| <= 0              | Failed                      | Replaced next quarter             |

## Macro Shock Parameters

## Market Size AR(1) Process

$$\log(M_t) = \mu + \rho * \log(M_{t-1}) + \sigma * \epsilon_t$$

| Parameter   | Symbol   | Value |
|-------------|----------|-------|
| Drift       | $\mu$    | 0.005 |
| Persistence | $\rho$   | 0.95  |
| Volatility  | $\sigma$ | 0.05  |

## Risk-Free Rate Process

$$r_t = \max(0.005, \min(0.05, r_{t-1} + \sigma_r * \epsilon_t))$$

| Parameter      | Value                     |
|----------------|---------------------------|
| Starting value | 0.01/quarter (4% annual)  |
| Volatility     | 0.002/quarter             |
| Floor          | 0.005/quarter (2% annual) |
| Ceiling        | 0.05/quarter (20% annual) |

## Event Probabilities (Per Quarter)

| Event                      | Per-Firm Probability             | Industry Probability             |
|----------------------------|----------------------------------|----------------------------------|
| Publicized adverse event   | 3%                               | ~14% (at least one firm)         |
| Partial clinical hold      | 2% (higher if AE rate above avg) | --                               |
| Full clinical hold         | 0.5%                             | --                               |
| Class-wide clinical hold   | --                               | 0.3%                             |
| Academic breakthrough      | --                               | 5%                               |
| Supply chain disruption    | 2% per firm                      | --                               |
| Regulatory pricing event   | --                               | ~0.5% (~15% cumulative over 80Q) |
| Insurance coverage mandate | --                               | ~0.4% (~25% cumulative over 80Q) |

## Stochastic R&D Success

### Generation Advance Check

Each quarter, for each firm, if cumulative product R&D exceeds the minimum threshold:

$$P(\text{success}) = \text{base\_rate} * \min(2.0, (\text{cumulative} / \text{threshold\_mid})^{0.5})$$

| Transition     | Threshold (min) | Threshold (mid) | Base Rate | Max P/quarter |
|----------------|-----------------|-----------------|-----------|---------------|
| Gen 1 -> Gen 2 | \$400M          | \$500M          | 0.12      | 0.24          |
| Gen 2 -> Gen 3 | \$800M          | \$1,000M        | 0.08      | 0.16          |
| Gen 3 -> Gen 4 | \$1,500M        | \$2,000M        | 0.06      | 0.12          |

"Threshold (min)" is the absolute minimum cumulative spend to have any chance. "Threshold (mid)" is the calibrated center of the range. Spending beyond mid improves probability but with diminishing returns (the square root).

### Process R&D (COGS Reduction)

$$\text{cogs\_reduction\_pct} = 0.22 * (1 - \exp(-\text{cumulative\_process\_rd} / 120\_000\_000))$$

This is an exponential saturation: fast gains initially, diminishing returns, maximum 22% reduction within a generation.

## Delivery R&D

Same stochastic check as product R&D, with separate thresholds:

| Transition           | Threshold (min) | Base Rate | Requires                 |
|----------------------|-----------------|-----------|--------------------------|
| IV -> Subcutaneous   | \$100M          | 0.15      | Nothing (can do with Gen |
| SubQ -> Oral         | \$300M          | 0.10      | Gen 2 compound           |
| Oral -> Gene therapy | \$800M          | 0.06      | Gen 3 compound           |

## Scoring Parameters

### Equity IRR Computation

Terminal value for surviving firms at end of simulation:

```
terminal_equity_value = equity_price_final * shares_outstanding
```

For defaulted firms: terminal equity = 0 (or waterfall residual, usually 0). For acquired firms: terminal equity = acquisition proceeds to equity holders.

Cash flows to equity: [-IPO investment, +dividends, +buybacks, +terminal\_value] IRR computed on this cash flow stream.

This is the canonical formula. Doc 11's "terminal enterprise value" is a separate metric for reporting, NOT used in the IRR calculation.

### Environment Rating Scale

| Score | Meaning                                    |
|-------|--------------------------------------------|
| 1-2   | Unrealistic, inconsistent, unfair          |
| 3-4   | Below average; notable problems            |
| 5-6   | Adequate; functional but some issues       |
| 7-8   | Good; realistic and engaging               |
| 9-10  | Excellent; highly immersive and consistent |
